Statistical methods for investigating the determinants of growth, exports and employment in China

UFR de Mathématique et d'Informatique

Master 1 Statistique 2009-2010

PIAO Donghong

Supervisor: Professor Bertrand KOEBEL

Abstract

This paper examines the effects of employment and exports on China's economic growth. Based on export-augmented Cobb-Douglas production function, a set of panel data is used to estimate the contribution of economic growth from exports and employment. We find that both the impacts of exports and employment are positive in the China's economic growth. Besides, we also analyse these effects in different regions in China. The result reveals that the relationship between exports and GDP in the east coastal region is stronger than that in the other regions; the similar situation happens to employment.

Key words: Economic growth, export, employment, panel data.

Acknowledgement

This paper could not be finished without the help and support of many people who are gratefully acknowledged here.

First of all, I would like to show my deepest gratitude to my supervisor, Professor Bertrand KOEBEL, who has led me to doing a research and offered me valuable ideas, suggestions and criticisms with his profound knowledge and rich research experience.

What's more, I wish to extend my thanks to *UFR de Mathématique et d'Informatique*. I owe special thanks to my professor, Armelle Guillou, for her help in the last year.

Thanks are also due to my friends, who never failed to give me great encouragement and suggestions. Special thanks should go to Miss. Li Yuanyuan for her brainstorming with me when I failed coming up with ideas.

At last but not least, I would like to thank my family for their support all the way, I am thankful to all my family members for their thoughtfulness and encouragement.

1. Introduction

In the ranking of the largest economies of the world measured by the gross domestic products (GDP), China stood at the 15th position in 1978, but in 2008 the ranking placed it at the 3th position and this year it will be at the 2nd position instead of Japan. In the recent 30 years, exports and GDP have increased rapidly (Figure 1) in China. Exports have grown from 164 19 million yuan to 9 936 306 million yuan, while GDP has risen from 364 500 million yuan to 30 285 300 million yuan with an average growth rate over 9%¹. China has also experienced a process of rapid expansion in employment (Figure 2) during this period - 402 million persons were employed in 1978, compared to 775 million persons in 2008, which has played a very important role in China's economic development.

The relationship between foreign trades and economic growth has been investigated in China. Although most of the empirical work supports that the exports led economic growth in China, there is no overall consensus on this issue. Yongjun Li and Justin Yifu Lin (2003) think, according their estimation, a 10% increase in exports will lead to a 1% increase of GDP on average. Shen Lisheng and Wu Zhenyu (2003) gave a method for measuring the contribution to GDP from exports through the I/O table analysis. They found that the rate of contribution from per unit export decreased from 1997 to 2001.

Additional, researches based on provincial data have also been carried on these years. Christer Ljungwall (2006) analyzed the relationship between GDP and export at the provincial level, and he found that the export-led growth (ELG) hypothesis is validated in 13 of the 27 provinces in the sample. He Dong and Zhang Wenlang (2010) using input-output analysis showed that the relationship between GDP and exports is stronger in the more developed coastal areas than in the less developed inland areas.

¹ All data, unless otherwise noted, do not include Hong Kong, Macao and Taiwan.

Source: *Comprehensive Statistical Data and Materials on 60 Years of New China*

This paper uses a panel data set of 30 provinces, municipalities and autonomous regions in China from 1978 to 2008 to analyse the determinants of China's economic growth and tries to find the contribution of China's economic growth from employment and exports. Besides using static panel data models, dynamic panel data model is also introduced to

analyse the effects of exports and employment to economic growth. Furthermore, we examine these effects in different regions.

This paper is divided into 5 parts. Part 1 is the introduction. The next part presents the empirical method, in which we will mainly introduce panel data models and the correspondent estimations. The third part introduces our empirical model and the data we choose. The fourth part is the key part, where we will report and analyse the results of the estimation. And finally summaries and conclusions are provided.

2. Empirical method

2.1 Introduction of panel data models

In recent years, panel data estimation approaches have become widely used. Panel (or longitudinal) data are both cross-sectional and time-series. There are multiple entities, each of which has repeated measurements at different time periods. Therefore, the variables in panel data models have double subscripts with i denoting individuals and t denoting time. As for our study, a panel data set is used for GDP, capital stock, employment and exports in each province of China from 1978 to 2008.

2.2 Static panel data models

Static panel data models is that independent variables do not include lagged dependent variables. Generally, the panel model is given by:

$$Y_{it} = \alpha_{it} + X_{it}' \beta_{it} + \mu_i + \varepsilon_{it} \quad i = 1, \dots, N; t = 1, \dots, T \quad (2-1)$$

where Y_{it} (1×1) is the dependent variable, $X_{it} = (X_{it1}, \dots, X_{itk})'$ ($1 \times k$) are dependent variables, α_{it} (1×1) and $(\beta_{it1}, \dots, \beta_{itk})'$ ($1 \times k$) are the parameters to estimate and μ_i and ε_{it} are the unobserved effects. This model is under a set of assumptions:

$$H_1: \mu_i \sim IDD(0, \sigma_\mu)$$

$$H_2: \varepsilon_{it} \sim IDD(0, \sigma_\varepsilon)$$

$$H_3: \mu_i \text{ is independent of } \varepsilon_{it}.$$

There are three situations of panel data models:

- 1) $\alpha_i = \alpha_j, \beta_i = \beta_j$: Using ordinary least squares (OLS) method will provide unbiased, efficient, and consistent estimations.
- 2) $\alpha_i \neq \alpha_j, \beta_i = \beta_j$: Including fixed effects and the random effects, estimation using separately the least squares dummy variable model (LSDV), the generalized least squares (GLS) and the feasible generalized least squares (FGLS).
- 3) $\alpha_i \neq \alpha_j, \beta_i \neq \beta_j$: This model is more complex.

There are two important regressions: the fixed effects regression and the random effects regression. Fixed effects regression is the model to use when we want to control for omitted variables that differ between cases but are constant over time. It lets us use the changes in the variables over time to estimate the effects of the independent variables on our dependent variable, and is the main technique used for analysis of panel data. Statistically, fixed effects are always a reasonable thing to do with panel data (they always give consistent results) but they may not be the most efficient model to run. Random effects will give you better P-values as they are a more efficient estimator. We can utilize the Hausman test to determine which model to be used.

2.3 Dynamic panel data models

In many economic issues, the future is often correlated with the past. This is to say that y_{it} is related to its past realizations y_{it-1} . The dynamic nature of the model reflects the real relationship between the independent and dependent variables more accurately. Thus, the dynamic panel data model is specified as below.

$$y_{it} = \alpha_{it} + \gamma y_{it-1} + x_{it}' \beta_{it} + \mu_i + \varepsilon_{it} \quad i = 1, \dots, N; t = 1, \dots, T \quad (2-2)$$

Under a set of assumptions:

$$H_1: \mu_i \sim IDD(0, \sigma_\mu),$$

$$H_2: \varepsilon_{it} \sim IDD(0, \sigma_\varepsilon).$$

$$H_3: \mu_i \text{ is independent of } \varepsilon_{it}.$$

However, the introduction of the lagged dependent variable can pose a variety of problems. For example, the dependent variables Y_{it} and Y_{it-1} are functions of μ_i , and estimation using OLS will result in biased, inefficient, and inconsistent estimates. Arellano and Bond(1991) used Generalized method of moments (GMM) to estimate dynamic panel data models.

Taking the first difference of the model and we can get:

$$y_{it} - y_{it-1} = \gamma(y_{it-1} - y_{it-2}) + (x'_{it} - x'_{it-1})\beta + \varepsilon_{it} - \varepsilon_{it-1} \quad (2-3)$$

Then we have:

$$\Delta Y_t = (\Delta Y_{t-1} \quad \Delta X_t) \begin{pmatrix} \gamma \\ \beta \end{pmatrix} + \Delta \varepsilon_t \quad (2-4)$$

where $\Delta Y_i = (y_{i1}, \dots, y_{iT})'$, $\Delta X_i = (x_{i1}, \dots, x_{iT})'$, and $\Delta \varepsilon_i = (\varepsilon_{i1}, \dots, \varepsilon_{iT})'$.

We can find y_{i0} is highly correlated with $y_{i1} - y_{i0}$ and is uncorrelated to $\varepsilon_{i2} - \varepsilon_{i1}$.

Assuming that the explanatory variables are strictly exogenous, we can use all of them as additional instruments for estimating the parameters. That is, the instrumental variables matrix Z_i is given by

$$Z_i = \begin{pmatrix} (y_{i0}, x'_{i0}, \dots, x'_{iT}) & 0 & \dots & 0 \\ 0 & (y_{i0}, y_{i1}, x'_{i0}, \dots, x'_{iT}) & \dots & 0 \\ \vdots & 0 & \ddots & 0 \\ 0 & 0 & \dots & (y_{i0}, y_{i1}, \dots, y_{iT-2}, x'_{i0}, \dots, x'_{iT}) \end{pmatrix} \quad (2-5)$$

It is orthogonal if

$$E(Z_i' \Delta \varepsilon_i) = 0 \quad (2-6)$$

And the sample moment conditions are given by:

$$\frac{1}{n} \sum_{i=1}^N Z_i' \Delta \varepsilon_i = 0 \quad (2-7)$$

We can get the criterion function as below:

$$q = \left(\frac{1}{n} \sum_{i=1}^N \Delta \varepsilon_i' Z_i \right) \hat{\Phi}^{-1} \left(\frac{1}{n} \sum_{i=1}^N Z_i' \Delta \varepsilon_i \right) \quad (2-8)$$

Where,

$$\begin{aligned} \Phi &= \text{var} \left(\frac{1}{\sqrt{N}} \sum_{i=1}^N Z_i' \Delta \varepsilon_i \right) \\ &= \frac{1}{N} \text{E} \left(\sum_{i=1}^N Z_i' \Delta \varepsilon_i \Delta \varepsilon_i' Z_i \right) \\ &= \frac{1}{N} \sum_{i=1}^N Z_i' \text{E}(\Delta \varepsilon_i \Delta \varepsilon_i') Z_i \end{aligned} \quad (2-9)$$

In fact,

$$\text{E}(\Delta \varepsilon_i \Delta \varepsilon_i') = \sigma_\varepsilon^2 (\mathbf{I}_N \otimes G) \quad (2-10)$$

Where,

$$G = \begin{pmatrix} 2 & -1 & 0 & \cdots & 0 & 0 & 0 \\ -1 & 2 & -1 & \cdots & 0 & 0 & 0 \\ \vdots & \vdots & 0 & \ddots & \vdots & \vdots & \vdots \\ 0 & 0 & 0 & \cdots & -1 & 2 & -1 \end{pmatrix} \quad (2-11)$$

From (2-9) and (2-10) we can get:

$$\Phi = \frac{1}{N} \sigma_\varepsilon^2 \sum_{i=1}^N Z_i' G Z_i \quad (2-12)$$

Taking the derivative of the criterion function:

$$\frac{\partial q}{\partial \begin{pmatrix} \gamma \\ \beta \end{pmatrix}} = \left(\frac{1}{N} \sum_{i=1}^N (\Delta Y_{i-1}, \Delta X_i)' Z_i \right) \left(\frac{1}{N} \sum_{i=1}^N Z_i' G Z_i \right)^{-1} \left(\frac{1}{N} \sum_{i=1}^N Z_i \left[\Delta Y_i - (\Delta Y_{i-1}, \Delta X_i) \begin{pmatrix} \gamma \\ \beta \end{pmatrix} \right] \right) \quad (2-13)$$

Take $\frac{\partial q}{\partial \begin{pmatrix} \gamma \\ \beta \end{pmatrix}} = 0$, then we can get the estimates using the GMM:

$$\begin{aligned} \begin{pmatrix} \gamma \\ \beta \end{pmatrix}_{GMM} &= \left\{ \left(\frac{1}{N} \sum_{i=1}^N (\Delta Y_{i-1}, \Delta X_i)' Z_i \right) \left(\frac{1}{N} \sum_{i=1}^N Z_i' G Z_i \right)^{-1} \left(\frac{1}{N} \sum_{i=1}^N Z_i' (\Delta Y_{i-1}, \Delta X_i) \right) \right\}^{-1} \\ &\quad - \left\{ \left(\frac{1}{N} \sum_{i=1}^N (\Delta Y_{i-1}, \Delta X_i)' Z_i \right) \left(\frac{1}{N} \sum_{i=1}^N Z_i' G Z_i \right)^{-1} \left(\frac{1}{N} \sum_{i=1}^N Z_i' Y_i \right) \right\} \end{aligned} \quad (2-14)$$

When independent variables x_{it} are predetermined variables, when $s < t$, $E(x_{it}\varepsilon_{it}) \neq 0$, when $s \geq t$, $E(x_{it}\varepsilon_{it}) = 0$. Therefore, only $(y_{i0}, x'_{i0}, \dots, x'_{i,s-1})$ is instrumental variables of the model (2-3) at the time s . In this situation, the instrumental variables of estimation GMM is as below:

$$Z_i = \begin{pmatrix} (y_{i0}, x'_{i0}, x'_{i1}) & 0 & \dots & 0 \\ 0 & (y_{i0}, y_{i1}, x'_{i0}, x'_{i1}, x'_{i2}) & \dots & 0 \\ 0 & 0 & \dots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \dots & (y_{i0}, y_{i1}, \dots, y_{i,T-2}, x'_{i0}, x'_{i1}, \dots, x'_{i,T-1}) \end{pmatrix} \quad (2-15)$$

Thus, we can get the estimations using GMM when x_{it} are predetermined variables according to (2-14) and (2-15).

From (2-5) and (2-15), we can know that there may be too many instrumental variables (IV) in the model, which is not reasonable. Generally, we just use the IV that is useful and adjust the matrix of instruments accordingly.

In addition, Arellano and Bond (1991) also proposed the test for over-identifying restrictions, and the statistic of Sargan is given as below:

$$m = \Delta \hat{\varepsilon}' Z \left[\sum_{i=1}^n Z_i'(\Delta \hat{\varepsilon}_i)(\Delta \hat{\varepsilon}_i)' Z_i \right]^{-1} Z'(\Delta \hat{\varepsilon})$$

Under the null hypothesis of Sargan test,

$$m \sim \chi^2(L - K)$$

where L is the rank of the instrumental variables matrix and K is number of parameters.

3. Empirical model & Data selection

3.1 Empirical model

This approach is based on a Cobb-Douglas production function; that is, output is a function of capital, labor, and a term for total factor productivity. And in order to analyse the contribution of exports we consider the export-augmented Cobb-Douglas production function:

$$Y = A K^\alpha L^\beta E^\gamma \quad (3-1)$$

where Y denotes the aggregate output; A denotes the efficiency parameter; K denotes the capital stock; L denotes the labor input; and E denotes the exports. Taking logarithmic transformation to linearize (3-1) we have:

$$\ln Y = \ln A + \alpha \ln K + \beta \ln L + \gamma \ln E \quad (3-2)^2$$

Therefore, we can get the model as below:

$$\ln Y_{it} = \beta_0 + \beta_1 \ln K_{it} + \beta_2 \ln L_{it} + \beta_3 \ln E_{it} + \mu_i + \varepsilon_{it} \quad (3-3)$$

where $\beta_0, \beta_1, \beta_2, \beta_3$ are the parameters to be estimated.

$\ln Y_{it}$ denotes the natural logarithm of aggregate output in the i^{th} province in the t^{th} year.

$\ln K_{it}$ denotes the natural logarithm of capital stock in the i^{th} province in the t^{th} year.

² Using the neoclassical trade theory (NTT) we will have the same model. NTT will be evaluated in a neoclassical production function framework incorporating an additional factor of production (exports) into the production function because the exports must have a positive effect on aggregate output. The augmented neoclassical production function is specified as follows:

$$Y = f(K, L, E)$$

The econometric specification of this relationship will be captured in various bivariate (aggregate output and exports) models without exogenous variables and various bi-variate models with exogenous variables, all expressed in logarithmic form. Below is a representation of an econometric model of bi-variate form with exogenous variables:

$$\ln Y = \beta_0 + \beta_1 \ln K + \beta_2 \ln L + \beta_3 \ln E$$

Which is the same as the export-augmented Cobb-Douglas production function.

$\ln L_{it}$ denotes the natural logarithm of labor input in the i^{th} province in the t^{th} year.

$\ln E_{it}$ denotes the natural logarithm of exports in the i^{th} province in the t^{th} year.

μ_i denotes the unobserved effects of the i^{th} province.

ε_{it} denotes the unobserved effects of the i^{th} province in the t^{th} year.

3.2 Data selection

Aggregate output

The real GDP of each province of China is used to express aggregate output³ and take 1952 as the base year, which is used throughout this paper.

$$\text{Real GDP} = \frac{\text{Nominal GDP}}{\text{GDP deflator}}$$

We use this formula as follow to calculate GDP deflator.

$$D_{it} = \begin{cases} 1 & , t = 1952 \\ \text{GDP}_{it} / [\text{GDP}_{it-1} * (I_{it} / 100)] & , t > 1952 \end{cases}$$

Where D_{it} denotes the GDP deflator of the i^{th} province in the t^{th} year; GDP_{it} denotes the nominal GDP deflator of the i^{th} province in the t^{th} year; I_{it} denotes the GDP indices of the i^{th} province in the t^{th} year (Data are calculated at constant prices and preceding year=100)⁴.

Capital stock

Wu (2007) has proposed a method of calculating capital stock for China's regional economies⁵ and we use this kind of data. The general technique of calculating capital stock values is the perpetual inventory approach (PIM):

³ Chongqing which is created on 14 March 1997 was part of Sichuan province. Therefore, in this paper we amalgamate the data of Chongqing and Sichuan.

⁴ Owing to absence of Hainan's GDP indices, we utilize the average GDP indices of the whole China.

⁵ Capital stock data are in 1952 constant prices from 1952-2006. Wu(2007) indicate: "*Economists specializing in the Chinese economy have been puzzled by the discrepancy between national and regional data....One possible explanation is that since the mid 1990s capital has become very mobile in China and a lot of cross-regional investment has taken place. As a result, some investment and hence capital formation have been claimed by both the home and hosting regions.*"

$$K_{i,t} = (1 - \delta)K_{i,t-1} + \Delta K_{i,t}$$

where $K_{i,t}$ is the value of capital stock for the i^{th} region in the t^{th} year; $\Delta K_{i,t}$ is the real value of incremental capital stock and δ is the rate of depreciation⁶.

Labor input

Labor input should be measured by the standard labor time and labor intensity, but we cannot gain associated data. Therefore, in this paper we use the number of employment of each province of China to represent labor input⁷.

Exports

The real exports of each province of China are used, and we do not consider the trade between any two provinces.

⁶ The rates of depreciation are different for different regions.

⁷ These data are from *Comprehensive Statistical Data and Materials on 60 Years of New China* Published by *China Statistics Press*.

4. Results

4.1 Static panel data models in the whole country

The data used in this study are publicly available from government agencies. The National Bureau of Statistics of China publishes data on nominal GDP and we transform them to real GDP taking 1952 as the base year. The capital stock is calculated in the constant prices in 1952 according to Wu (2007). Table 1 reports the summary of the descriptive statistics on the natural logarithm of GDP, employment, capital stock, exports in the whole country (include 30 provinces) from 1978 to 2008 and Table 2 reports the correlation coefficients of these variables.

Table 1. The summary of the variables in the whole country

Variable	Max	Mean	Min	Std Dev	Median	Lower Quartile	Upper Quartile
Ln(GDP)	8.76	5.70	1.86	1.31	5.71	4.85	6.62
Ln(Employment)	8.76	7.21	4.53	0.97	7.39	6.67	7.94
Ln(Capital)	9.65	6.83	2.20	1.27	6.79	5.95	7.77
Ln(Export)	8.56	2.90	-3.70	2.28	3.06	1.58	4.35

Table 2. Correlation coefficients of variables in the whole country

	Ln(GDP)	Ln(Employment)	Ln(Capital)	Ln(Export)
Ln(GDP)	1			
Ln(Employment)	0.67604	1		
Ln(Capital)	0.97387	0.5903	1	
Ln(Export)	0.90166	0.46293	0.88022	1

According to Hausman test⁸ ($Pr < 0.0001$), we use fixed estimation method. The results are reported in Table 3. As we can see, the estimates of the coefficients of the logarithm capital and labor are significant at 1% level. In this study, we get the estimations for the contributions of capital and labor are 48.1% and 41.1%, respectively. What's more, the estimate of the coefficient of exports is small (0.0583) but also significant at 1% level, which means that exports has an important impact on GDP. To be specific, GDP increases 0.06% when exports increase 1%. In the whole country, the impacts of employment and exports are both positive for the economic growth. However, the impact of employment is stronger than exports.

As for the positive contributions to GDP of employment and exports, there are several reasons. First, due to the economic reform in China since 1978, a lot of foreign enterprises have entered and invested in China. Therefore, much employment was provided. That is one of the most important reasons for China's economic growth. And in the recent years, China's policy and the huge number of cheap labor (Not only is unskilled labor has low-priced, highly trained labor is also cheap) have attracted a lot of enterprises of original equipment manufacturer (OEM) like Foxconn. That constitutes the inducement of the exports growth. The growth of exports has led to the economic growth,

⁸ The hausman test tests the null hypothesis that the coefficients estimated by the efficient random effects estimator are the same as the ones estimated by the consistent fixed effects estimator.

which in turn attracted more enterprises into China at the same time.

Table 3. Results of static panel data models in whole country

Variable	Estimate	Standard Error	t Value	Pr > t
Intercept	-0.25356	0.3458	-0.73	0.4636
Ln(Employment)	0.411236***	0.0447	9.21	<.0001
Ln(Capital)	0.481176***	0.0166	28.91	<.0001
Ln(Export)	0.058316***	0.00552	10.56	<.0001
R-Square	0.9929	Hausman Test		Pr<.0001

***, **, * denote statistically significant at 1%, 5%, and 10% level respectively.

4.2 Dynamic panel data models in the whole country

Static panel data model does not consider dynamic effects of GDP. In fact, lagged values of GDP may have effects on current GDP. Therefore, in this part we apply the dynamic panel data model to consider the influence of the lagged GDP. According to (2-2), we get the empirical model as below:

$$\ln Y_{it} = \beta_0 + \gamma \ln Y_{it-1} + \beta_1 \ln K_{it} + \beta_2 \ln L_{it} + \beta_3 \ln E_{it} + \mu_i + \varepsilon_{it} \quad (3-4)$$

Since the result of the estimation using OLS is biased, inefficient, and inconsistent estimates, we estimate the coefficient using GMM that Arellano and Bond (1991) proposed for the dynamic panel data model. In the equation (3-4) there is the lag of dependent variable, so we take the first difference of the model and get the empirical model as follows:

$$\Delta \ln Y_{it} = \gamma \Delta \ln Y_{it-1} + \beta_1 \Delta \ln K_{it} + \beta_2 \Delta \ln L_{it} + \beta_3 \Delta \ln E_{it} + \Delta \varepsilon_{it} \quad (3-5)$$

Estimation by a two-step GMM method is chosen here and five lags of the dependent variables are used as instruments.

Because the number of instrumental variable (IV) is more than number of endogenous variables, we should use Sargan test to check the over-identifying restrictions. According to Table 4, we can find that Sargan test pass the test at 10% level, so over-identifying restrictions test is valid. Thus, IV is uncorrelated with the error term, which shows that IV is valid⁹.

Table 4. Results of dynamic panel data models in the whole country

Variable	Estimate	Standard Error	t Value	Pr > t
$\Delta \ln(GDP)_1$	0.018693***	0.00228	8.18	<.0001
$\Delta \ln(Employment)$	0.242764***	0.0252	9.65	<.0001
$\Delta \ln(Capital)$	0.098254***	0.0142	6.93	<.0001
$\Delta \ln(Export)$	0.010037***	0.00174	5.78	<.0001
Sargan Test Prob > ChiSq 1.0000				

***, **, * denote statistically significant at 1%, 5%, and 10% level respectively.

$\ln(GDP)_1$ denotes the one lag of $\ln(GDP)$.

Table 4 reports the results of dynamic panel data model in the whole country. We can find that all the estimates are significant at 1% level and all coefficients are positive including

⁹ The null hypothesis of Sargan test is that the error term is uncorrelated with the instruments.

the estimate of $\Delta \ln(GDP)_1$, which captures the dynamic relationship in the growth of GDP. For this, we can explain as follows. Firstly, the growth of GDP in the last year will bring more capital input this year; therefore, GDP will grow rapidly. Secondly, the rapid growth of GDP in the last term will attract more investors to come into China. Thirdly, anticipation in economy play an important role, and the situation of the growth of GDP in the last term is the base of the anticipation in this term. Therefore, the rapid growth in the last term leads to the growth in the current term.

The effects of $\Delta \ln(\text{Employment})$ and $\Delta \ln(\text{Export})$ are also significant and positive for the growth of GDP. From the results, GDP will increase 0.24% when the employment increases 1%, whereas it grows 0.01% when the exports grow 1%.

4.3 Analysis of the static models in three geographical regions

There are the glaring differences of the China's economic development in different regions. The contributions to GDP from employment and exports are different in various regions. In 1978, China transforms its planned economy into a market economy, the east region reformed firstly. Therefore, it develops more rapidly than the other regions. Generally, we divide China into three geographical regions. The detail of the division is reported in Table 5.

Figure 3 shows the growth of real GDP in different regions. It is obvious that the economy grows faster in the eastern region than the others, and the west region develops slowest. And from Figure 4, real exports of the east region also grow fast, especially in the last decade. Although we can find significant differences in the three regions of China in the respect of both economic growth and exports, Figure 5 indicates that the employment of the three regions grows almost in the same speed. Due to this, it's necessary to analyse the cause of economic growth respectively.

Table 5. The division of China's geographical regions

Region	The provinces, municipalities and autonomous regions	Number
East of China	Beijing, Tianjin, Hebei, Liaoning, Shanghai, Jiangsu, Zhejiang, Fujian, Guangdong, Guangxi, Hainan, Shandong.	12
Middle of China	Shanxi, Inner Mongolia, Jilin, Heilongjiang, Anhui, Jiangxi, Henan, Hubei, Hunan.	9
West of China	Sichuan (including Chongqing), Guizhou, Yunnan, Tibet, Shaanxi, Gansu, Ningxia, Qinghai, Xinjiang.	9

Figure 3 Growth of RealGDP in three regions

Figure 4 Growth of export in three regions

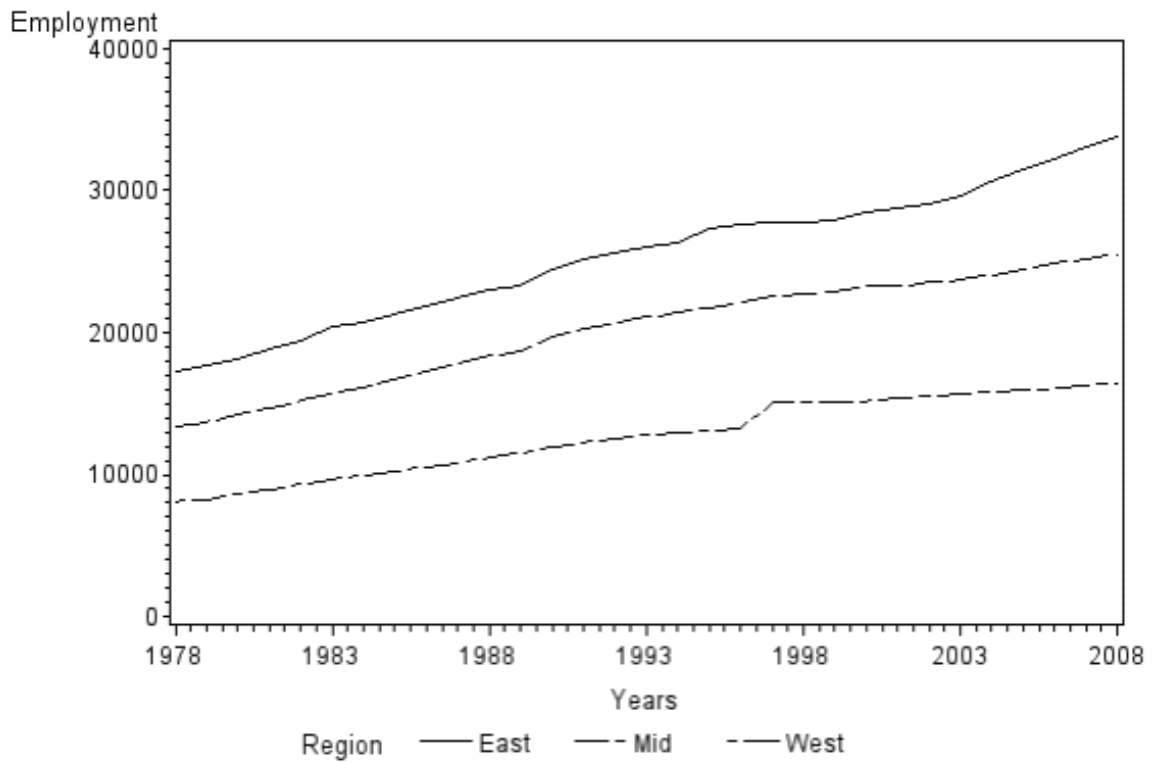

Figure 5 Growth of employment in three regions

In this part, based on the static panel data model we introduce three dummy variables,

D_e , D_m , D_w which are specified as follow:

$$De_{it} = \begin{cases} 1, & \text{The provinces in the eastern region.} \\ 0, & \text{The provinces in the other regions.} \end{cases}$$

$$Dm_{it} = \begin{cases} 1, & \text{The provinces in the middle region.} \\ 0, & \text{The provinces in the other regions.} \end{cases}$$

$$Dw_{it} = \begin{cases} 1, & \text{The provinces in the western region.} \\ 0, & \text{The provinces in the other regions.} \end{cases}$$

Therefore, the model is represented as below:

$$\ln Y_{it} = \beta_0 + \beta_1 \ln K_{it} + \beta_{2e}(De_{it} \times \ln L_{it}) + \beta_{2m}(Dm_{it} \times \ln L_{it}) + \beta_{2w}(Dw_{it} \times \ln L_{it}) \\ + \beta_{3e}(De_{it} \times \ln E_{it}) + \beta_{3m}(Dm_{it} \times \ln E_{it}) + \beta_{3w}(Dw_{it} \times \ln E_{it}) + \mu_i + \varepsilon_{it}$$

where e , m , w denote eastern, middle and western region respectively. The variables have the same meaning with (3-3).

Table 6 reports the summary of the variables in different regions and Table 7 contains the results of the estimation of the coefficients in different regions. We can find all the estimations are significant at 1% level except the intercept. The contribution of GDP from the exports in the eastern area is higher than that in the other two regions, which shows the same result as He Dong and Zhang Wenlang (2010). GDP of the eastern region grows rapidly from 1978, because many foreign direct investments (FDI) were created in many provinces of this region, such as Guangdong, Fujian, Shanghai and so on. That is also why the last global economic crisis brought the greatest impact for the eastern region.

In the western area, although the economic growth is less than the other region, there are a lot of natural resources, such as coal, fossil fuels, rock and mineral resources. Therefore, the contribution of GDP from the exports in the west region achieves almost the level of middle region.

However, the employment is always the most important factor for the growth of GDP. When the employment increases 1% in the eastern region, GDP will increase 0.54%, whereas in the middle and western regions they are respectively 0.30% and 0.37%.

Table 6. The summary of the variables in different regions

Region	N Obs	Variable	Max	Mean	Min	Std Dev
East	372	Ln(GDP)	8.76	6.25	2.57	1.27
		Ln(Employment)	8.73	7.35	5.40	0.87
		Ln(Capital)	9.65	7.32	4.41	1.24
		Ln(Export)	8.56	4.38	-1.96	2.01
Mid	279	Ln(GDP)	7.89	5.76	4.01	0.90
		Ln(Employment)	8.67	7.57	6.47	0.54
		Ln(Capital)	8.86	6.85	4.99	0.94
		Ln(Export)	5.30	2.47	-2.43	1.51
West	279	Ln(GDP)	8.27	4.87	1.86	1.32
		Ln(Employment)	8.76	6.67	4.53	1.18
		Ln(Capital)	8.81	6.16	2.20	1.27
		Ln(Export)	5.67	1.33	-3.70	2.03

Table 7. Parameter estimates of static models by region

Variable	Estimate	Standard Error	t Value	Pr > t
Intercept	0.990119	0.4152	2.38	0.0173
$\ln(\text{export})_e$	0.07686***	0.00716	10.73	<.0001
$\ln(\text{export})_w$	0.053552***	0.0071	7.54	<.0001
$\ln(\text{export})_m$	0.059051***	0.00917	6.44	<.0001
$\ln(\text{employment})_e$	0.53595***	0.0598	8.96	<.0001
$\ln(\text{employment})_w$	0.365053***	0.0538	6.79	<.0001
$\ln(\text{employment})_m$	0.30275***	0.0732	4.13	<.0001
$\ln(\text{capital})$	0.363309***	0.02	18.13	<.0001
R-Square	0.8235	Hausman Test		Pr<.0001

***, **, * denote statistically significant at 1%, 5%, and 10% level respectively.

Table 8. Wald test of coefficient constraints in static models

Null hypothesis	Statistic	Pr > ChiSq	Result
$\ln(\text{export})_e = \ln(\text{export})_m$	2.76	0.0969*	Reject
$\ln(\text{export})_e = \ln(\text{export})_w$	7.33	0.0068*	Reject
$\ln(\text{export})_w = \ln(\text{export})_m$	0.28	0.5985	Accept
$\ln(\text{employment})_e = \ln(\text{employment})_m$	7.72	0.0055*	Reject
$\ln(\text{employment})_e = \ln(\text{employment})_w$	5.98	0.0145**	Reject
$\ln(\text{employment})_w = \ln(\text{employment})_m$	33.02	<.0001***	Reject

***, **, * denote statistically significant at 1%, 5%, and 10% level respectively.

Table 8 reports the Wald test of coefficient constraints, we cannot accept null hypothesis of Wald test except the hypothesis ($\ln(\text{export})_w = \ln(\text{export})_m$). To sum up, we can think that there exist differences of the effect of the exports on GDP among various regions. However, the difference between the effects of the exports on GDP in the western and middle regions is not statistically evident. On the other hand, the contribution of the exports in the east is different from the other two regions and it much higher than the other regions. For employment, there are also the glaring differences in three regions.

4.4 Analysis of the dynamic models in three geographical regions

From the dynamic panel data model in the whole country, we find the growth of GDP in the last term is significant and have the positive effect for the growth of GDP. Therefore, we have the reason to believe the dynamic panel data models are more reasonable to

analyze the determinants of the China's economic growth. We also build three dummy variables, D_e , D_m , D_w which are specified as follows.

$$De_{it} = \begin{cases} 1, & \text{The provinces in the east region.} \\ 0, & \text{The provinces in the other regions.} \end{cases}$$

$$Dm_{it} = \begin{cases} 1, & \text{The provinces in the middle region.} \\ 0, & \text{The provinces in the other regions.} \end{cases}$$

$$Dw_{it} = \begin{cases} 1, & \text{The provinces in the west region.} \\ 0, & \text{The provinces in the other regions.} \end{cases}$$

Therefore, we can get the model as below.

$$\begin{aligned} \Delta \ln Y_{it} = & \gamma \Delta \ln Y_{it-1} + \beta_3 \Delta \ln K_{it} + \beta_1 (De_{it} \times \Delta \ln L_{it}) + \beta_1 (Dm_{it} \times \Delta \ln L_{it}) \\ & + \beta_1 (Dw_{it} \times \Delta \ln L_{it}) + \beta_2 (De_{it} \times \Delta \ln E_{it}) + \beta_2 (Dm_{it} \times \Delta \ln E_{it}) \\ & + \beta_2 (Dw_{it} \times \Delta \ln E_{it}) + \Delta \varepsilon_{it} \end{aligned}$$

Firstly, we run Sargan test which pass the test at 10% level, so over-identifying restrictions test is valid. We estimate the coefficients by a two step GMM method and five lags of the dependent variables are used as instruments. Table 9 reports the results of parameter estimates using dynamic model. It shows that the coefficients are positive and significant at the level 1%, excluding those of the employment in the western region, exports in the middle and western regions. The same as the static panel data model in the whole country, the growth rate in the last term has the positive effect on the growth in the current term. Compared to the static model, we can find that the relationship between the growth rate of employment and the economic growth rate in eastern region is less strong, which is also true for the relationship between the growth rate of export and GDP.

In addition, table 10 reports the results of Wald test of coefficient constraints in dynamic models, we can find there are differences between the effects of exports in the eastern

region and in the other regions in the economic growth. Whether in static models or dynamic models, the impact of export in the eastern area is always positive and significant. Therefore, we can say the exports in the eastern area are quit important for its economic growth.

Table 9 . Parameter estimates of dynamic models by region

Variable	Estimate	Standard Error	t Value	Pr > t
$\Delta \text{Ln}(GDP)_1$	0.018998***	0.00315	6.04	<.0001

Sargan Test Prob > ChiSq 1.0000

***, **, * denote statistically significant at 1%, 5%, and 10% level respectively.

Table 10. Wald test of coefficient constraints in dynamic models

Null hypothesis	Statistic	Pr > ChiSq	Result
$\Delta \ln(\text{export})_e = \Delta \ln(\text{export})_m$	5.35	0.0207**	Reject
$\Delta \ln(\text{export})_e = \Delta \ln(\text{export})_w$	5.46	0.0195**	Reject
$\Delta \ln(\text{export})_w = \Delta \ln(\text{export})_m$	0.11	0.7382	Accept
$\Delta \ln(\text{employment})_e = \Delta \ln(\text{employment})_m$	0.15	0.695	Accept
$\Delta \ln(\text{employment})_e = \Delta \ln(\text{employment})_w$	9.69	0.0019***	Reject
$\Delta \ln(\text{employment})_w = \Delta \ln(\text{employment})_m$	0.76	0.3824	Accept

***, **, * denote statistically significant at 1%, 5%, and 10% level respectively.

Considering the negative and insignificant estimates of some coefficients, which does not make sense in the economic context, the results of the dynamic panel data in different regions are not quite satisfying. This might be due to the data we use in this study, which measure the exports without considering the trade between two provinces.

5. Conclusion

Since the reform (1978) in China, the exports increased more than 600% and they rise at a higher rate than the economic growth rate, the employment almost doubled, increasing from 402 million persons in 1978 to 775 million persons in 2008. According to our estimation, both the exports and the employment are important factors in the China's economic growth. Although the contribution for economic growth from the exports is not so much as that from the employment in the whole country, they both have the positive effects in economic growth. From the dynamic models, we can find the effect of economic growth in the last term is also positive in the economic growth in the current year, which shows the dynamic nature of the economic growth. From 1978, a lot of foreign companies entered the Chinese market and have set up a large number of plants which provided many jobs. Due to the number of the low-priced labor, exports exhibit the evident superiority. Therefore, we can conclude that beside labor and capital, exports also lead to the rapid growth of China's economy in the past 30 years.

In different regions, we find that there exist the glaring differences in respect of the effects of exports and employment on the economic growth. The economic growth of the east coastal region, which develops more rapidly and is more economically open to the world than the other regions, has a stronger relationship with its exports. Yet in the middle and western regions, the effects of exports do not show evident differences. The impact of employment is also the most important in the eastern region. Although the western area is less developed in China, the increasing of the government's investment promotes the growth of employment, which is the most important factor in the economic growth in the west. Due to the crucial part played by the employment, the fact that a huge number of cheap labors from the middle and west of China go to the east coastal area to find a job may be the one of the most important reasons of the rapid growth of GDP in the eastern region.

We acknowledge that the specification of the model, the selection of the estimation method and the selection of data will affect the results; therefore, the further improvement is expected.
